

Exercise J6 - Gamma-ray attenuation coefficients

January 28, 2024

1 Introduction

The goal of this exercise is to measure γ -ray attenuation coefficients for several materials, using monoenergetic γ source and a scintillation detector.

2 Required reading

1. Interaction of γ -rays with matter: photoelectric absorption, Compton scattering, pair production ([1]-2.III.A).
2. Attenuation coefficient ([1]-2.III.B)
3. Principles of operation of scintillation detectors ([1]-8.II, 9.I)
4. Electronic signal processing (preamplifier, amplifier, multichannel analyzer) ([2]-14.1, 14.2, [1]-16.III, 18-III).
5. Energy resolution, energy calibration, efficiency calibration ([1]-4.V, 4.VI)
6. Statistical and systematical uncertainties in radiation measurements ([1]-3.II).
7. Decay schemes ([2]-1.1, 1.3).

3 Outline

1. Introduction to experimental setup: calibration sources, detectors, HV power supplies, analyzer and computer program.
2. Measurement of standard calibration sources.
3. Determination of measurement conditions, including amplifier gain and distance from the source.
4. Measurement of the background radiation.

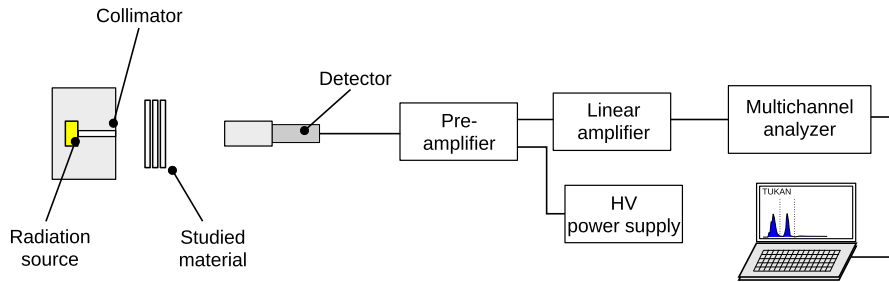

Figure 1: Overview of the experimental setup

5. Measurement of attenuation coefficient for different materials (aluminum, copper, iron, lead) for different thicknesses.
6. Measurement of materials thickness with calipers.

4 Data analysis

A laboratory report is a kind of essay, and it should be written with correct spelling and grammar. It should follow logical reasoning, keeping in mind that a person that never done the exercise before, should understand what were the objectives, methods and results.

It should be structured with sections like introduction, methods, results, and conclusions. The introduction should define the purpose of the experiment, put possible hypotheses to be tested, refer to previous studies, and briefly describe the method to be used. The main part, consisting of a more detailed description of the procedure and results, should include figures, and schemes, clearly presented, including labels, legends, units, and other elements. It is not needed to copy textbook knowledge, instead, it is better to select the key information on used methods and equipment and focus on the actual experiment and results. Numerical values should be presented with uncertainties. In the conclusions, one should discuss whether the result confirms expectations or predictions, how it compares to the literature, what is the source of discrepancies, or the main component of uncertainty, if something could be improved, etc.

Main analysis steps

1. Energy calibration of the detector
2. Analysis of attenuation curves for measured materials.
3. Determination of the attenuation coefficients.
4. Experimental uncertainties discussion.
5. Comparison of the results with literature data and discussion
